

MODELING FRACTURES AND BARRIERS AS INTERFACES FOR FLOW IN POROUS MEDIA*

VINCENT MARTIN[†], JÉRÔME JAFFRÉ[‡], AND JEAN E. ROBERTS[‡]

Abstract. We consider a fractured porous medium that is studied at a scale such that the fractures can be modeled individually. Models for flow in which the fractures are interfaces between subdomains are presented. These models take into account interactions between the fractures and the surrounding porous medium. Existence and uniqueness of the solution to the model problem are proved. Error estimates show convergence as $\mathcal{O}(\max\{h, d\})$ in the L^2 norm, where h is the mesh size and d the fracture width. Numerical experiments confirm the theoretical results.

Key words. fractures, faults, barriers, mixed finite elements, domain decomposition, flow in porous media

1. Introduction. We are concerned with flow of a single phase fluid in a fractured porous medium. Our study is carried out at a scale for which the fractures can be modeled individually. The fractures have a small width and are treated as interfaces between subdomains. We also assume that the fractures are filled with debris and that flow in the fractures respects Darcy's law; cf. [1].

We distinguish two types of fractures: fractures which have a permeability higher than that in the surrounding medium and those in which the permeability is lower than that in the surrounding medium. In a medium with the former type of fracture the fluid has a tendency to flow into the fracture and then along the fracture. In this case, one should not expect the Darcy velocity to be identical on the two sides of the fracture. Consequently, as the fracture is treated as an interface, the normal component of the velocity need not be continuous across this interface. An earlier model described by Alboin, Jaffré, and Roberts in [2] and [3] was based on the assumption that the permeability in the fracture was large and a jump in the normal component of the velocity across the interface was permitted.

However, when the fracture has a lower permeability, the fluid naturally tends to avoid the fracture, which represents, in fact, a geological barrier. Two geological layers separated by such a barrier have little communication. Thus, it is understandable that the pressure need not be the same on the two sides of the fracture. In this case the pressure is not continuous across the fracture-interface.

In this paper we present a model that generalizes the earlier model (see [2], [3]) so that it can handle both large and small permeability fractures. Indeed, the earlier model assumed the continuity of the pressure across the interface. This is no longer the case with the model presented here.

The model is derived through a process of averaging across the fracture. This process is carried out for the flow equation written in mixed form. One thereby obtains a flow equation along the interface that is coupled with flow equations in the neighboring subdomains. The main difference between this model and the previous one is that here nonstandard Robin type conditions are imposed at the interface. The Robin coefficient is proportional to the ratio of the permeability in the fracture to the fracture width. A parameter is introduced yielding a family of models. Existence and uniqueness of the solution of the mixed weak formulation of the problem are proved for certain values of the parameter. An error estimate is obtained for a particular choice of the parameter. Some numerical experiments show the quality of the results.

The simplest form of our model was presented in [12]. Others have also treated fractures as interfaces: in [6], Helmig et al. represented the fracture by lower dimensional finite elements. A model presented by Angot, Gallouët, and Herbin in [4] is based on Robin boundary conditions at the interface and assumes the continuity of the flux across the fracture. A model similar to ours for a certain value of the parameter was studied by Faille et al. in [10].

Remark. The fracture model developed here is for two- or three-dimensional spaces. Though numerical results are given only in the two-dimensional case, they could easily be carried out for three-dimensional problems. We have treated the case of a single linear or planar fracture. The fact that the fracture is linear or planar is simply for convenience. Intersecting fractures can be treated by requiring equal pressure and mass balance at the points (or curves) of intersection. This was done for the earlier model in [2]. However, implementation in the case of intersecting fractures in a three-dimensional model could easily become quite complicated. We are looking at an extension of the model to the two-phase flow problem but this is considerably more difficult.

In section 2, we describe the problem of flow in a domain containing a fracture. In section 3, the model problem is derived and in section 4 it is analyzed at the continuous level. In section 5 we obtain error estimates for the discrete model problem. In section 6 we give numerical results, and section 7 offers a domain decomposition formulation for the model problem.

2. Description of the problem. We suppose that Ω is a convex domain in \mathbb{R}^n , $n = 2$ or 3 , and we denote by $\Gamma = \partial\Omega$ the boundary of Ω . We suppose that the flow in Ω is governed by a conservation equation together with Darcy's law relating the gradient of the pressure p to the Darcy velocity \mathbf{u} :

$$(2.1) \quad \begin{aligned} \operatorname{div} \mathbf{u} &= q && \text{in } \Omega, \\ \mathbf{u} &= -\mathbf{K} \nabla p && \text{in } \Omega, \\ p &= \bar{p} && \text{on } \Gamma, \end{aligned}$$

where p is the pressure, \mathbf{u} the Darcy velocity, \mathbf{K} the hydraulic conductivity (or permeability) tensor, q a source term, and \bar{p} the given pressure on the boundary Γ . We suppose that \mathbf{K} is diagonal and that each diagonal entry K_{jj} , $j = 1, 2, \dots, n$, is positive and bounded above and away from 0,

$$0 < K_{\min} \leq K_{jj} \leq K_{\max}, \quad j = 1, 2, \dots, n, \quad \text{a.e. in } \Omega.$$

We suppose (see Figure 2.1) that the fracture Ω_f is a subdomain of Ω and that

FIG. 2.1. Left: The domain Ω with the fracture Ω_f . Right: The subdomains Ω_1 and Ω_2 separated by the fracture considered as an interface γ .

there is a hyperplane γ and a unit vector $\mathbf{n} = \mathbf{n}_1 = -\mathbf{n}_2$ normal to γ such that

$$\Omega_f = \left\{ x \in \Omega : x = s + r\mathbf{n} \text{ for some } s \in \gamma \right.$$

$$\left. \text{and some } r \text{ in the interval } \left(-\frac{d(s)}{2}, \frac{d(s)}{2} \right) \right\},$$

where $d(s)$ denotes the thickness of the fracture at $h \in \gamma$.

We also assume that $\bar{\Omega}_f$ separates Ω into two connected subdomains,

$$\Omega \setminus \bar{\Omega}_f = \Omega_1 \cup \Omega_2, \quad \Omega_1 \cap \Omega_2 = \emptyset.$$

We denote by Γ_i the part of the boundary of Ω_i shared with the boundary of Ω , $i = 1, 2, f$,

$$\Gamma_i = \partial\Omega_i \cap \Gamma, \quad i = 1, 2, f,$$

and we denote by γ_i the part of the boundary of Ω_i shared with the boundary of the fracture Ω_f , $i = 1, 2$,

$$\gamma_i = \partial\Omega_i \cap \partial\Omega_f \cap \Omega, \quad i = 1, 2.$$

Let η be the outward unit normal vector field on Γ .

If we denote by p_i , \mathbf{u}_i , \mathbf{K}_i , and q_i the restrictions of p , \mathbf{u} , \mathbf{K} , and q , respectively, to Ω_i , $i = 1, 2, f$, and by \bar{p}_i the restriction of \bar{p} to Γ_i , $i = 1, 2, f$, we can rewrite the above problem (2.1) as the following transmission problem:

$$(2.2) \quad \begin{aligned} \operatorname{div} \mathbf{u}_i &= q_i && \text{in } \Omega_i, \quad i = 1, 2, f, \\ \mathbf{u}_i &= -\mathbf{K}_i \nabla p_i && \text{in } \Omega_i, \quad i = 1, 2, f, \\ p_i &= \bar{p}_i && \text{on } \Gamma_i, \quad i = 1, 2, f, \\ p_i &= p_f && \text{on } \gamma_i, \quad i = 1, 2, \\ \mathbf{u}_i \cdot \mathbf{n} &= \mathbf{u}_f \cdot \mathbf{n} && \text{on } \gamma_i, \quad i = 1, 2. \end{aligned}$$

3. Derivation of the model. In the model presented here the fracture is treated as an interface between the domains Ω_1 and Ω_2 . The model is obtained by averaging along the line segments $[\mathbf{s} - d(\mathbf{s})\mathbf{n}, \mathbf{s} + d(\mathbf{s})\mathbf{n}]$, $\mathbf{s} \in \gamma$, normal to γ . Treatment

of the conservation equation is straightforward: there results a conservation equation on the surface γ with a source term representing flow into the fracture from the subdomains. Darcy’s law is a vector equation, and averaging the components tangential to γ yields a Darcy law in γ relating the tangential component of the gradient of the averaged pressure to the tangential component of the averaged Darcy velocity. The system of these two equations in γ is then of the same form as the system in each of the subdomains, except that we have here a source term representing the exchange between γ and the subdomains. The remaining equation involving the normal components of the vectors in Darcy’s law must be exploited to obtain boundary conditions along γ for the systems in Ω_1 and Ω_2 ; however, averaging this equation yields only a formula for the difference of the trace along γ of the pressure in Ω_1 and that of the pressure in Ω_2 . Several possibilities exist for closing the system.

3.1. Averaging across the fracture. First, decompose \mathbf{u}_f as $\mathbf{u}_f = \mathbf{u}_{f,\mathbf{n}} + \mathbf{u}_{f,\tau}$ with $\mathbf{u}_{f,\mathbf{n}} = \mathbf{u}_f \cdot \mathbf{n} \mathbf{n}$ (recall that $\mathbf{n} = \mathbf{n}_1 = -\mathbf{n}_2$). Let ∇_τ and div_τ denote the tangential gradient and divergence operators and $\nabla_{\mathbf{n}}$ and $\text{div}_{\mathbf{n}}$ the normal gradient divergence operators.

3.1.1. Averaging the conservation equation. With the above notation, the first equation of (2.2) for $i = f$ may be rewritten as

$$(3.1) \quad \text{div}_{\mathbf{n}} \mathbf{u}_f + \text{div}_\tau \mathbf{u}_f = q_f \quad \text{in } \Omega_f.$$

Integrating in the direction normal to the fracture, one obtains

$$(3.2) \quad \mathbf{u}_f \cdot \mathbf{n}|_{\gamma_2} - \mathbf{u}_f \cdot \mathbf{n}|_{\gamma_1} + \text{div}_\tau \mathbf{U}_f = Q_f \quad \text{on } \gamma,$$

where $\mathbf{U}_f = \int_{-d/2}^{d/2} \mathbf{u}_{f,\tau} d\mathbf{n}$ and $Q_f = \int_{-d/2}^{d/2} q_f d\mathbf{n}$. Then, using the continuity of the fluxes across γ_1 and γ_2 , the last equation of (2.2) for $i = 1$ and 2, we may write

$$(3.3) \quad \text{div}_\tau \mathbf{U}_f = Q_f + (\mathbf{u}_1 \cdot \mathbf{n}_1|_{\gamma_1} + \mathbf{u}_2 \cdot \mathbf{n}_2|_{\gamma_2}) \quad \text{on } \gamma.$$

This is the conservation equation on γ with the additional source term $\mathbf{u}_1 \cdot \mathbf{n}_1|_{\gamma_1} + \mathbf{u}_2 \cdot \mathbf{n}_2|_{\gamma_2}$.

3.1.2. Averaging Darcy’s law. The second equation of (2.2) for $i = f$ may be written

$$(3.4) \quad \begin{aligned} \mathbf{u}_{f,\tau} &= -\mathbf{K}_{f,\tau} \nabla_\tau p_f & \text{in } \Omega_f, \\ \mathbf{u}_{f,\mathbf{n}} &= -\mathbf{K}_{f,\mathbf{n}} \nabla_{\mathbf{n}} p_f & \text{in } \Omega_f. \end{aligned}$$

Again, integrating in the direction normal to the fracture, one obtains from the first equation of (3.4)

$$(3.5) \quad \mathbf{U}_f = -\mathbf{K}_{f,\tau} d \nabla_\tau P_f \quad \text{on } \gamma,$$

where $P_f = \frac{1}{d} \int_{-d/2}^{d/2} p_f d\mathbf{n}$ and where we have assumed that $\mathbf{K}_{f,\tau}$ is constant along the segments $[\mathbf{s} - d(\mathbf{s} \cdot \mathbf{n}), \mathbf{s} + d(\mathbf{s} \cdot \mathbf{n})]$. This is Darcy’s law in the $(n-1)$ -dimensional domain γ . Together, (3.3) and (3.5) give a flow equation in γ with a source term representing the flow from the subdomains Ω_1 and Ω_2 into the fracture. The remaining equation, the second equation of (3.4), must now be used to give boundary conditions along γ for the systems in Ω_1 and Ω_2 which allow for a pressure difference from one side of γ to the other.

Integrating the remaining equation, the second equation (3.4), in the direction normal to the fracture, one obtains

$$(3.6) \quad \int_{-d/2}^{d/2} \mathbf{u}_{f,\mathbf{n}} \cdot \mathbf{n} \, d\mathbf{n} = -\mathbf{K}_{f,\mathbf{n}}(p_f|_{\gamma_2} - p_f|_{\gamma_1}).$$

The integral $\int_{-d/2}^{d/2} \mathbf{u}_{f,\mathbf{n}} \cdot \mathbf{n} \, d\mathbf{n}$ has not been computed but can be approximated using the trapezoidal rule,

$$\int_{-d/2}^{d/2} \mathbf{u}_{f,\mathbf{n}} \cdot \mathbf{n} \, d\mathbf{n} \approx \frac{d}{2}(\mathbf{u}_f \cdot \mathbf{n}|_{\gamma_2} + \mathbf{u}_f \cdot \mathbf{n}|_{\gamma_1}) = \frac{d}{2}(\mathbf{u}_2 \cdot \mathbf{n}|_{\gamma_2} + \mathbf{u}_1 \cdot \mathbf{n}|_{\gamma_1}),$$

where we have used the continuity along γ_1 and γ_2 of the fluxes, the fifth equation of (2.2). Now using the continuity along γ_1 and γ_2 of the pressures, the fourth equation of (2.2), the second equation of (3.4) is approximated by

$$(3.7) \quad \frac{1}{2}(\mathbf{u}_2 \cdot \mathbf{n}|_{\gamma_2} + \mathbf{u}_1 \cdot \mathbf{n}|_{\gamma_1}) = -\mathbf{K}_{f,\mathbf{n}} \frac{p_2|_{\gamma_2} - p_1|_{\gamma_1}}{d},$$

or using the notation

$$(3.8) \quad \alpha_f = \frac{2\mathbf{K}_{f,\mathbf{n}}}{d},$$

$$-\mathbf{u}_1 \cdot \mathbf{n}_1|_{\gamma_1} + \alpha_f p_1|_{\gamma_1} = -\mathbf{u}_2 \cdot \mathbf{n}_2|_{\gamma_2} + \alpha_f p_2|_{\gamma_2}.$$

This gives an equation for the pressure difference across the fracture.

Boundary conditions along γ , I. To close the system and obtain boundary conditions on γ for the problems in Ω_1 and Ω_2 one last equation is necessary. As (3.7) gives the difference between the pressures across γ , a natural choice is to obtain an equation for the sum of the pressures on γ by supposing that the average pressure across the fracture P_f is also the average of the pressures on the boundaries γ_1 and γ_2 . Thus to calculate $p_2|_{\gamma_2}$ and $p_1|_{\gamma_1}$, we use the following two equations:

$$(3.9) \quad p_2|_{\gamma_2} - p_1|_{\gamma_1} = \frac{d}{2K_f}(\mathbf{u}_2 \cdot \mathbf{n}_2|_{\gamma_2} - \mathbf{u}_1 \cdot \mathbf{n}_1|_{\gamma_1}),$$

$$p_2|_{\gamma_2} + p_1|_{\gamma_1} = 2P_f.$$

Summing and subtracting the two equations in (3.9), one gets

$$(3.10) \quad -1/2 \mathbf{u}_1 \cdot \mathbf{n}_1|_{\gamma_1} + \alpha_f p_1|_{\gamma_1} = -1/2 \mathbf{u}_2 \cdot \mathbf{n}_2|_{\gamma_2} + \alpha_f P_f,$$

$$-1/2 \mathbf{u}_2 \cdot \mathbf{n}_2|_{\gamma_2} + \alpha_f p_2|_{\gamma_2} = -1/2 \mathbf{u}_1 \cdot \mathbf{n}_1|_{\gamma_1} + \alpha_f P_f.$$

Boundary conditions along γ , II. If we approximate the value of p_f at the center of the fracture by P_f and the value of $(\mathbf{u}_f \cdot \mathbf{n})$ at the center of the fracture by the averaged flux, $\frac{\mathbf{u}_f \cdot \mathbf{n}_f|_{\gamma_1} + \mathbf{u}_f \cdot \mathbf{n}_f|_{\gamma_2}}{2}$, and then average across each half of the fracture in the same way that we averaged across the entire width of the fracture above, we obtain the following two equations:

$$(3.11) \quad \frac{1}{4}(3\mathbf{u}_2 \cdot \mathbf{n}|_{\gamma_2} + \mathbf{u}_1 \cdot \mathbf{n}|_{\gamma_1}) = -\mathbf{K}_{f,\mathbf{n}} \frac{p_f|_{\gamma_2} - P_f}{d/2},$$

$$\frac{1}{4}(\mathbf{u}_2 \cdot \mathbf{n}|_{\gamma_2} + 3\mathbf{u}_1 \cdot \mathbf{n}|_{\gamma_1}) = -\mathbf{K}_{f,\mathbf{n}} \frac{P_f - p_f|_{\gamma_1}}{d/2}$$

or

$$(3.12) \quad \begin{aligned} -3/4 \mathbf{u}_1 \cdot \mathbf{n}_1|_{\gamma_1} + \alpha_f p_1|_{\gamma_1} &= -1/4 \mathbf{u}_2 \cdot \mathbf{n}_2|_{\gamma_2} + \alpha_f P_f, \\ -3/4 \mathbf{u}_2 \cdot \mathbf{n}_2|_{\gamma_2} + \alpha_f p_2|_{\gamma_2} &= -1/4 \mathbf{u}_1 \cdot \mathbf{n}_1|_{\gamma_1} + \alpha_f P_f. \end{aligned}$$

These equations can be subtracted to recover (3.7) or the first equation of (3.9), but addition does not yield the second equation of (3.9), but (after dividing by $d/2$)

$$(3.13) \quad -K_f \frac{p_2|_{\gamma_2} + p_1|_{\gamma_1} - 2P_f}{d^2/4} = \frac{\mathbf{u}_2 \cdot \mathbf{n}|_{\gamma_2} - \mathbf{u}_1 \cdot \mathbf{n}|_{\gamma_1}}{d}.$$

The two equations of (3.12) can also be combined to obtain

$$(3.14) \quad \begin{aligned} \mathbf{u}_1 \cdot \mathbf{n}_1|_{\gamma_1} &= -\frac{K_f}{d}(4P_f - 3p_1|_{\gamma_1} - p_2|_{\gamma_2}), \\ \mathbf{u}_2 \cdot \mathbf{n}_2|_{\gamma_2} &= -\frac{K_f}{d}(4P_f - p_1|_{\gamma_1} - 3p_2|_{\gamma_2}). \end{aligned}$$

Boundary conditions along γ , III. The two equations of (3.14) suggest another possibility:

$$(3.15) \quad \begin{aligned} \mathbf{u}_1 \cdot \mathbf{n}_1|_{\gamma_1} &= -\mathbf{K}_f \frac{p_f|_{\gamma_1} - P_f}{d/2}, \\ \mathbf{u}_2 \cdot \mathbf{n}_2|_{\gamma_2} &= -\mathbf{K}_f \frac{p_f|_{\gamma_2} - P_f}{d/2} \end{aligned}$$

or, using the coefficient α_f defined in (3.8),

$$(3.16) \quad \begin{aligned} -\mathbf{u}_1 \cdot \mathbf{n}_1|_{\gamma_1} + \alpha_f p_1|_{\gamma_1} &= \alpha_f P_f, \\ -\mathbf{u}_2 \cdot \mathbf{n}_2|_{\gamma_2} + \alpha_f p_2|_{\gamma_2} &= \alpha_f P_f. \end{aligned}$$

From these two equations we can again recover (3.7) or the first equation of (3.9), but the second equation of (3.9) is replaced by

$$(3.17) \quad -K_f \frac{p_2|_{\gamma_2} + p_1|_{\gamma_1} - 2P_f}{d^2/2} = \frac{\mathbf{u}_2 \cdot \mathbf{n}|_{\gamma_2} - \mathbf{u}_1 \cdot \mathbf{n}|_{\gamma_1}}{d}$$

or

$$p_2|_{\gamma_2} + p_1|_{\gamma_1} = 2P_f - \frac{d}{2K_f}(\mathbf{u}_2 \cdot \mathbf{n}|_{\gamma_2} - \mathbf{u}_1 \cdot \mathbf{n}|_{\gamma_1}).$$

Boundary conditions along γ , the general case. The three sets of equations (3.10), (3.12), and (3.16) can be rewritten in the form

$$(3.18) \quad -\xi \mathbf{u}_1 \cdot \mathbf{n}_1|_{\gamma_1} + \alpha_f p_1|_{\gamma_1} = -(1 - \xi) \mathbf{u}_2 \cdot \mathbf{n}_2|_{\gamma_2} + \alpha_f P_f,$$

$$(3.19) \quad -\xi \mathbf{u}_2 \cdot \mathbf{n}_2|_{\gamma_2} + \alpha_f p_2|_{\gamma_2} = -(1 - \xi) \mathbf{u}_1 \cdot \mathbf{n}_1|_{\gamma_1} + \alpha_f P_f$$

for the values $\xi = 1/2$, $\xi = 3/4$, and $\xi = 1$, respectively.

4. Model problem for the fracture. We study the following model problem, which is an extension of the previous work (see [3], [2]).

4.1. Strong formulation of the model problem. The parameter ξ is a positive real number that will be determined later on. For common applications, this parameter should be such that $\xi \in]1/2, 1]$. We use the notation ∇_τ (and, respectively, div_τ) for the tangential gradient (and, respectively, tangential divergence) operators along the fracture γ . We assume that the index i of the subdomains varies in $Z/2Z$ (so that $2 + 1 = 1$). Posing $\alpha_f = \frac{2\mathbf{K}_{f,n}}{d}$, the problem can be written

$$\begin{aligned}
 (4.1) \quad & \mathbf{u}_i = -\mathbf{K}_i \nabla p_i && \text{in } \Omega_i, \quad i = 1, 2, \\
 & \text{div } \mathbf{u}_i = q_i && \text{in } \Omega_i, \quad i = 1, 2, \\
 & \mathbf{u}_f^\tau = -\mathbf{K}_{f,\tau} d \nabla_\tau p_f && \text{in } \gamma, \\
 & \text{div}_\tau \mathbf{u}_f^\tau = q_f + (\mathbf{u}_1 \cdot \mathbf{n}_1|_\gamma + \mathbf{u}_2 \cdot \mathbf{n}_2|_\gamma) && \text{in } \gamma, \\
 & -\xi \mathbf{u}_i \cdot \mathbf{n}_i + \alpha_f p_i = \alpha_f p_f - (1 - \xi) \mathbf{u}_{i+1} \cdot \mathbf{n}_{i+1} && \text{in } \gamma, \quad i = 1, 2, \\
 & p_i = \bar{p}_i && \text{on } \Gamma_i, \quad i = 1, 2, \\
 & p_f = \bar{p}_f && \text{on } \partial\gamma.
 \end{aligned}$$

This system can be seen as a domain decomposition problem, with nonstandard and nonlocal boundary conditions between the subdomains. The third equation in (4.1) represents Darcy’s law in the direction tangential to the fracture. The fourth equation in (4.1) models mass conservation inside the fracture. A source term $(\mathbf{u}_1 \cdot \mathbf{n}_1|_{\gamma_1} + \mathbf{u}_2 \cdot \mathbf{n}_2|_{\gamma_2})$ is introduced to take into account the contribution of the subdomain flows to the fracture flow. The fifth equation in (4.1) is a Robin boundary condition for the subdomain Ω_i with a dependence with the pressure in the fracture p_f and also with neighboring subdomain Ω_{i+1} ’s fluxes. This last dependence disappears only when ξ is equal to 1, and this case will be seen to be important for the domain decomposition formulation below (see section 7).

This fifth equation in (4.1) is equivalent to

$$(4.2) \quad p_i|_\gamma = p_f + \frac{\xi}{\alpha_f} \mathbf{u}_i \cdot \mathbf{n}_i - \frac{1 - \xi}{\alpha_f} \mathbf{u}_{i+1} \cdot \mathbf{n}_{i+1} \quad \text{on } \gamma, \quad i = 1, 2.$$

It is in this form that Robin boundary conditions are expressed in mixed formulation. If ξ is greater than $1/2$, we can also write

$$(4.3) \quad \mathbf{u}_2 \cdot \mathbf{n}_2|_{\gamma_2} + \mathbf{u}_1 \cdot \mathbf{n}_1|_{\gamma_1} = \frac{\alpha_f}{2\xi - 1} (p_2|_{\gamma_2} + p_1|_{\gamma_1} - 2p_f),$$

$$(4.4) \quad \mathbf{u}_2 \cdot \mathbf{n}_2|_{\gamma_2} - \mathbf{u}_1 \cdot \mathbf{n}_1|_{\gamma_1} = \alpha_f (p_2|_{\gamma_2} - p_1|_{\gamma_1}).$$

Remark. The difference between this model and the model with pressure continuous across the $(n - 1)$ -dimensional fracture (see [2], [3]) is that, in the earlier model, equations (4.2) were replaced by $p_2|_{\gamma_2} = p_1|_{\gamma_1} = p_f$. This corresponded to the assumption $\frac{1}{\alpha_f} = \frac{d}{2K_f} \approx 0$ made previously (large permeability and small width in the fracture).

Remark. The model depends actually on two physical, fracture-dependent coefficients: the product $\mathbf{K}_{f,\tau} d$ and the ratio $\mathbf{K}_{f,n}/d$. The first coefficient is related to the jump in the normal component of the velocity (noncontinuity of the Darcy velocity across the fracture). The second is related to the pressure jump (noncontinuity of pressure across the fracture).

The coefficient $\mathbf{K}_{f,\tau} d$ represents the equivalent permeability for the flow along the fracture. When this coefficient is of the same order as the permeability in the other

subdomains ($\mathbf{K}_{f,\tau} d \approx K_i, i = 1, 2$), i.e., when the fracture permeability is sufficiently large, the flow along the fracture interacts with the flow in the rocks. In this case, the jump of the Darcy velocity across the fracture ($\mathbf{u}_1 \cdot \mathbf{n}_1|_{\gamma_1} + \mathbf{u}_2 \cdot \mathbf{n}_2|_{\gamma_2}$) is generally not zero, because it is the contribution of the rock flow to the fracture flow. This result is in agreement with the asymptotic analysis study by Hung and Sánchez-Palencia [11], where the fracture permeability was large. One example of this type of behavior is shown in section 6.1.

The coefficient $\mathbf{K}_{f,\mathbf{n}}/d$ ($= \alpha_f/2$) represents an equivalent “resistivity” across the fracture. Let us assume that the fracture permeability is small and that the coefficient is of the same order as the permeability in the subdomains ($\mathbf{K}_{f,\mathbf{n}}/d \approx K_i, i = 1, 2$). In this case, the fluid barely flows along the fracture and the normal velocity jump is almost zero. Equations (4.3), (4.4) become, after dividing the second equation by 2, equations (4.5), (4.6), which are similar to the transmission equations of [4]. This result is also in agreement with the asymptotic analysis study by Sánchez-Palencia [17], where the fracture permeability was small. One example of this type of behavior is shown in section 6.2,

$$(4.5) \quad \mathbf{u}_2 \cdot \mathbf{n}_2|_{\gamma_2} + \mathbf{u}_1 \cdot \mathbf{n}_1|_{\gamma_1} = 0,$$

$$(4.6) \quad \mathbf{u}_2 \cdot \mathbf{n}_2|_{\gamma_2} = \frac{\mathbf{K}_{f,\mathbf{n}}}{d}(p_2|_{\gamma_2} - p_1|_{\gamma_1}).$$

4.2. Weak formulation of the model problem. We will need the following Hilbert spaces M and \mathbf{W} . It is necessary to assume more regularity than the $\mathcal{H}(\text{div}, *)$ regularity (used commonly for the mixed finite element methods) in order to take into proper account the Robin boundary conditions (see [16, pp. 589–590], for instance),

$$\begin{aligned} M &= \{r = (r_1, r_2, r_\gamma) \in L^2(\Omega_1) \times L^2(\Omega_2) \times L^2(\gamma)\}, \\ \mathbf{W} &= \{\mathbf{v} = (\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_f) \in \mathcal{H}(\text{div}, \Omega_1) \times \mathcal{H}(\text{div}, \Omega_2) \times \mathcal{H}(\text{div}_\tau, \gamma) : \\ &\quad \mathbf{v}_i \cdot \mathbf{n}_i \in L^2(\gamma), \quad i = 1, 2\}, \end{aligned}$$

equipped with the norms

$$\begin{aligned} \|r\|_M^2 &= \sum_{i=1}^2 \|r_i\|_{0,\Omega_i}^2 + \|r_f\|_{0,\gamma}^2, \\ \|\mathbf{v}\|_W^2 &= \sum_{i=1}^2 (\|\mathbf{v}_i\|_{0,\Omega_i}^2 + \|\text{div } \mathbf{v}_i\|_{0,\Omega_i}^2) + \|\mathbf{v}_f\|_{0,\gamma}^2 + \|\text{div}_\tau \mathbf{v}_f\|_{0,\gamma}^2 + \sum_{i=1}^2 \|\mathbf{v}_i \cdot \mathbf{n}_i\|_{0,\gamma}^2. \end{aligned}$$

Let the bilinear forms $\alpha_\xi : \mathbf{W} \times \mathbf{W} \rightarrow \mathbb{R}$ and $\beta : \mathbf{W} \times M \rightarrow \mathbb{R}$ be defined by

$$\begin{aligned} \alpha_\xi(\mathbf{u}, \mathbf{v}) &= \sum_{i=1}^2 (K_i^{-1} \mathbf{u}_i, \mathbf{v}_i)_{\Omega_i} + ((K_{f,\tau} d)^{-1} \mathbf{u}_f, \mathbf{v}_f)_\gamma \\ &\quad + \sum_{i=1}^2 \left(\frac{1}{\alpha_f} [\xi \mathbf{u}_i \cdot \mathbf{n}_i - (1 - \xi) \mathbf{u}_{i+1} \cdot \mathbf{n}_{i+1}], \mathbf{v}_i \cdot \mathbf{n}_i \right)_\gamma, \\ \beta(\mathbf{u}, r) &= \sum_{i=1}^2 (\text{div } \mathbf{u}_i, r_i)_{\Omega_i} + (\text{div}_\tau \mathbf{u}_f, r_f)_\gamma - \left(\sum_{i=1}^2 \mathbf{u}_i \cdot \mathbf{n}_i, r_f \right)_\gamma. \end{aligned}$$

Let the linear forms $L_q : M \rightarrow \mathbb{R}$ and $L_d : \mathbf{W} \rightarrow \mathbb{R}$ be defined by

$$L_q(r) = \sum_{i=1}^2 (q_i, r_i)_{\Omega_i} + (q_f, r_f)_\gamma,$$

$$L_d(\mathbf{v}) = \sum_{j=1}^2 (\mathbf{v}_j \cdot \mathbf{n}_j, \bar{p}_j)_{\Gamma_j} + (\mathbf{v}_f \cdot \mathbf{n}_f, \bar{p}_f)_{\partial\gamma}.$$

With these spaces and forms, one can easily see that the weak form of (4.1) may be written as follows:

$$(4.7) \quad \begin{aligned} &\mathbf{u} \in \mathbf{W}, p \in M, \\ &\alpha_\xi(\mathbf{u}, \mathbf{v}) - \beta(\mathbf{v}, p) = -L_d(\mathbf{v}) \quad \forall \mathbf{v} \in \mathbf{W}, \\ &\beta(\mathbf{u}, r) = L_q(r) \quad \forall r \in M. \end{aligned}$$

4.3. Existence and uniqueness of the solution. We assume that the right-hand side q is sufficiently regular (in M , for instance) and for simplicity that there are homogeneous Dirichlet boundary conditions imposed ($L_d = 0$). The domain and the fracture are also assumed to be smooth enough. Then we can state the following existence theorem.

THEOREM 4.1. *Assume that there exist two positive constants, $0 < K_{\min} < K_{\max}$, such that the permeabilities in the two subdomains and the coefficients $(\mathbf{K}_{f,\tau}d)$ and $(\mathbf{K}_{f,\mathbf{n}}/d) = \alpha_f/2$ are bounded by these constants: $0 < K_{\min} \leq K_i \leq K_{\max}$, $i = 1, 2$, $0 < K_{\min} \leq (\mathbf{K}_{f,\tau}d) \leq K_{\max}$, and $0 < K_{\min} \leq (\mathbf{K}_{f,\mathbf{n}}/d) \leq K_{\max}$. Assume also that the parameter $\xi > 1/2$. Then the model problem (4.7) has a unique solution.*

Proof. It is easy to check that \mathbf{W} and M are Hilbert spaces (see [16, p. 530]). The continuity of α_ξ over \mathbf{W}^2 and of β over $\mathbf{W} \times M$ is straightforward.

We introduce the subspace $\tilde{\mathbf{W}} = \{\mathbf{v} \in \mathbf{W} : \beta(\mathbf{v}, r) = 0 \forall r \in M\}$. To show existence and uniqueness of the solution of (4.7), it is sufficient to show that α_ξ is $\tilde{\mathbf{W}}$ -elliptic and that β satisfies the inf-sup condition (see [16, 7]); that is, there exist constants C_α and C_β such that

$$\inf_{\mathbf{v} \in \tilde{\mathbf{W}}} \frac{\alpha_\xi(\mathbf{v}, \mathbf{v})}{\|\mathbf{v}\|_{\tilde{\mathbf{W}}}^2} \geq C_\alpha, \quad \inf_{r \in M} \sup_{\mathbf{v} \in \tilde{\mathbf{W}}} \frac{\beta(\mathbf{v}, r)}{\|r\|_M \|\mathbf{v}\|_{\tilde{\mathbf{W}}}} \geq C_\beta.$$

To check that α_ξ is $\tilde{\mathbf{W}}$ -elliptic, we note that for $\mathbf{u} \in \tilde{\mathbf{W}}$, $\|\operatorname{div} \mathbf{u}_i\|_{0,\Omega_i} = 0$ and $\operatorname{div}_\tau \mathbf{u}_f = \mathbf{u}_1 \cdot \mathbf{n}_1 + \mathbf{u}_2 \cdot \mathbf{n}_2$. Thus

$$\|\mathbf{u}\|_{\tilde{\mathbf{W}}}^2 = \sum_{i=1}^2 \|\mathbf{u}_i\|_{0,\Omega_i}^2 + \|\mathbf{u}_f\|_{0,\gamma}^2 + \left\| \sum_{i=1}^2 \mathbf{u}_i \cdot \mathbf{n}_i \right\|_{0,\gamma}^2 + \sum_{i=1}^2 \|\mathbf{u}_i \cdot \mathbf{n}_i\|_{0,\gamma}^2.$$

For this $\mathbf{u} \in \tilde{\mathbf{W}}$, α_ξ can be written as

$$(4.8) \quad \begin{aligned} \alpha_\xi(\mathbf{u}, \mathbf{u}) &= \sum_{i=1}^2 (K_i^{-1} \mathbf{u}_i, \mathbf{u}_i)_{\Omega_i} + ((K_{f,\tau}d)^{-1} \mathbf{u}_f, \mathbf{u}_f)_\gamma \\ &\quad + \xi \sum_{i=1}^2 \left(\frac{\mathbf{u}_i \cdot \mathbf{n}_i}{\alpha_f^{1/2}}, \frac{\mathbf{u}_i \cdot \mathbf{n}_i}{\alpha_f^{1/2}} \right)_\gamma - 2(1-\xi) \left(\frac{\mathbf{u}_1 \cdot \mathbf{n}_1}{\alpha_f^{1/2}}, \frac{\mathbf{u}_2 \cdot \mathbf{n}_2}{\alpha_f^{1/2}} \right)_\gamma. \end{aligned}$$

The two first terms in (4.8) are easily estimated because the product $(\mathbf{K}_{f,\tau}d)$ and the permeabilities are bounded. Introducing $\phi_i = \alpha_f^{-1/2} \mathbf{u}_i \cdot \mathbf{n}_i$, $i = 1, 2$, the two other terms are equal to the quadratic form $B(\phi_1, \phi_2) = \xi \|\phi_1\|_{0,\gamma}^2 - 2(1 - \xi) (\phi_1, \phi_2)_\gamma + \xi \|\phi_2\|_{0,\gamma}^2$. The eigenvalues of B are 1 and $2\xi - 1$. Therefore, B is strictly elliptic if and only if $\xi > 1/2$. In this case, we obtain the inequality

$$\alpha_\xi(\mathbf{u}, \mathbf{u}) \geq K_{\max}^{-1} \left(\sum_{i=1}^2 \|\mathbf{u}_i\|_{0,\Omega_i}^2 + \|\mathbf{u}_f\|_{0,\gamma}^2 \right) + \min\{1, 2\xi - 1\} \sum_{i=1}^2 \left\| \frac{\mathbf{u}_i \cdot \mathbf{n}_i}{\alpha_f^{1/2}} \right\|_{0,\gamma}^2.$$

As the ratio $(\mathbf{K}_{f,\mathbf{n}}/d) = (\alpha_f/2)$ is bounded, and because $\|\sum_{i=1}^2 \mathbf{u}_i \cdot \mathbf{n}_i\|_{0,\gamma}^2 \leq 2 \sum_{i=1}^2 \|\mathbf{u}_i \cdot \mathbf{n}_i\|_{0,\gamma}^2$, for $\xi > 1/2$, we have

$$\begin{aligned} \alpha_\xi(\mathbf{u}, \mathbf{u}) &\geq K_{\max}^{-1} \left(\sum_{i=1}^2 \|\mathbf{u}_i\|_{0,\Omega_i}^2 + \|\mathbf{u}_f\|_{0,\gamma}^2 + \min\{1, 2\xi - 1\} \sum_{i=1}^2 \|\mathbf{u}_i \cdot \mathbf{n}_i\|_{0,\gamma}^2 \right) \\ &\geq 1/3 K_{\max}^{-1} \min\{1, 2\xi - 1\} \|u\|_{\mathbf{W}}^2. \end{aligned}$$

To see that β satisfies the inf-sup condition, given $r \in M$, we construct using the adjoint equation a $\mathbf{v} \in \mathbf{W}$ such that $\beta(\mathbf{v}, r) = \|r\|_M^2$ and $\|\mathbf{v}\|_{\mathbf{W}} \leq C \|r\|_M$, where C is the constant of elliptic regularity for the adjoint problem.

For $r = (r_1, r_2, r_\tau) \in M$, let $(\varphi_1, \varphi_2, \varphi_\gamma) \in H^2(\Omega_1) \times H^2(\Omega_2) \times H^2(\gamma)$ be the solution of

$$\begin{aligned} -\Delta\varphi &= \tilde{r} \quad \text{on } \Omega, \\ \varphi &= 0 \quad \text{on } \Gamma, \end{aligned}$$

where $\tilde{r} \in L^2(\Omega)$ is given by $\tilde{r}|_{\Omega_i} = r_i$, $i = 1, 2$, and

$$\begin{aligned} -\Delta_\tau\varphi_\gamma &= r_\tau \quad \text{on } \gamma, \\ \varphi_\gamma &= 0 \quad \text{on } \partial\gamma. \end{aligned}$$

Pose $\mathbf{v}_i = -\nabla\varphi|_{\Omega_i}$, $i = 1, 2$, and $\mathbf{v}_\gamma = -\nabla_\gamma\varphi_\gamma$, and note that $\text{div } \mathbf{v}_i = r_i \in L^2(\Omega_i)$, $i = 1, 2$, $\text{div}_\tau \mathbf{v}_\gamma = r_\tau \in L^2(\gamma)$, and $\mathbf{v}_1 \cdot \mathbf{n}_1 = -\mathbf{v}_2 \cdot \mathbf{n}_2 \in L^2(\gamma)$, because $\mathbf{v}_i \in (\mathcal{H}^1(\Omega))^d$. Thus $\mathbf{v} = (\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_\gamma) \in \mathbf{W}$ and $\beta(\mathbf{v}, r) = \|\tilde{r}\|_{0,\Omega}^2 + \|r_f\|_{0,\gamma}^2 = \|r\|_M^2$. We have

$$\begin{aligned} \|\mathbf{v}\|_{\mathbf{W}}^2 &= \|\tilde{r}\|_{0,\Omega}^2 + \|r_f\|_{0,\gamma}^2 + \|\nabla\varphi\|_{0,\Omega}^2 + \|\nabla_f\varphi_f\|_{0,\gamma}^2 + 2\|\mathbf{v}_1 \cdot \mathbf{n}_1\|_{0,\gamma}^2 \\ &\leq (1 + C(\Omega))\|\tilde{r}\|_{0,\Omega}^2 + (1 + C(\gamma))\|r\|_{0,\gamma}^2 + C(\Omega)\|\tilde{r}\|_{0,\Omega}^2. \quad \square \end{aligned}$$

Remark. The case in which the parameter $\xi = 1/2$, which appeared to be natural in the derivation of the model, corresponds to a stability limit for this model. In some numerical cases (for instance, in the cases presented in sections 6.1 and 6.2), the model problem gives very good results when the parameter ξ is equal to 1/2. But on some other numerical tests, instabilities appear (see, for instance, section 6.3).

Remark. One can prove in the same way that the discrete problem has a unique solution and that it converges toward the continuous solution of the model problem.

5. Interpretation of the discrete model and error estimates. We have seen in section 3 that one could derive the models by simply averaging the transmission problem under its strong formulation (2.2). In this section, we seek a simple error

FIG. 5.1. *Left: The domain Ω with a two-dimensional fracture Ω_f that is meshed with rectangles. Right: The one-dimensional fracture γ is meshed with the projection of the two-dimensional mesh on γ_1 (or γ_2).*

estimate for the model problem. For this purpose, we show that the discrete model problem for $\xi = 1$ and $2/3$ is actually none other than the discrete transmission problem under a specific domain decomposition formulation, with certain hypotheses concerning the approximation spaces and the mesh. Throughout this section, we will assume for simplicity that homogeneous Dirichlet boundary conditions are imposed on $\partial\Omega$.

5.1. Assumptions concerning the mesh. Let $\mathcal{T}_h = \cup \mathcal{T}_{h,i}$ be a conforming finite element partition of $\bar{\Omega} = \cup \bar{\Omega}_i$, $i = 1, 2, f$. The meshes $\mathcal{T}_{h,i}$, $i = 1, 2$, and the mesh $\mathcal{T}_{h,f}$ match on the interfaces γ_i , $i = 1, 2$. We assume henceforth that the following hypothesis concerning the mesh is true.

Hypothesis 1. We assume that the mesh \mathcal{T}_h of the whole domain Ω possesses the following shape: in the fracture Ω_f there exists only one strip of rectangular (two-dimensional) or parallelepiped (three-dimensional) cells, i.e., in three dimensions, each cell in the fracture is a parallelepiped with one face on γ_1 and the opposite face contained in γ_2 . (See Figure 5.1.)

Of course this hypothesis is quite restrictive, as it forbids in three dimensions a mesh made exclusively of tetrahedra. However, this assumption is made here only to show the link between the discrete transmission problem and the discrete model problem; therefore, this restriction is only for theoretical and not computational purposes.

5.2. The discrete transmission multiblock problem. Let us define the approximation spaces used in this paper:

$$\mathbf{Z}_i = H(\text{div}; \Omega_i), \quad i = 1, 2, f, \quad \mathbf{Z} = \bigoplus_{i=1,2,f} \mathbf{Z}_i,$$

$$N_i = L^2(\Omega_i), \quad i = 1, 2, f, \quad N = \bigoplus_{i=1,2,f} N_i = L^2(\Omega).$$

Let

$$\mathbf{Z}_{h,i} \times N_{h,i} \subset \mathbf{Z}_i \times N_i, \quad i = 1, 2, f,$$

be the usual mixed finite element approximation made of Raviart–Thomas (and Nédélec in three dimensions) spaces of lowest order (see [14], [15], [16]). We recall that $Z_{h,i}$ consists of some linear vector functions and that $N_{h,i}$ is made up of cellwise

constant scalar functions. Let

$$\mathbf{Z}_h = \bigoplus_{i=1,2,f} \mathbf{Z}_{h,i}, \quad N_h = \bigoplus_{i=1,2,f} N_{h,i}.$$

Let

$$\Lambda_h = Q_0(\gamma) = \mathbf{Z}_{h,i} \cdot \mathbf{n}_i|_{\gamma_i} = Q_0(\gamma_i), \quad i = 1, 2, f,$$

be the interface approximation space made up of functions constant on each face. For simplicity, but with an abuse of notation, we use the same notation Λ_h for the three spaces on the interfaces γ_1 , γ_2 , and γ , as the spaces actually do match.

We write the discrete mixed finite element approximation for the original problem (2.1) or, equivalently, for the transmission problem (2.2) introducing interelement multipliers $(\lambda_{h,1}, \lambda_{h,2})$ (see [5], [9], and the references therein). We seek $\mathbf{u}_h \in \mathbf{Z}_h$, $p_h \in N_h$, $(\lambda_{h,1}, \lambda_{h,2}) \in \Lambda_h^2$ such that

$$\begin{aligned} (5.1) \quad & (K_i^{-1} \mathbf{u}_h, \mathbf{v})_{\Omega_i} - (\operatorname{div} \mathbf{v}, p_h)_{\Omega_i} = -(\mathbf{v} \cdot \mathbf{n}_i, \lambda_{h,i})_{\gamma_i}, & \mathbf{v} \in \mathbf{Z}_{h,i}, \quad i = 1, 2, \\ & (K_f^{-1} \mathbf{u}_h, \mathbf{v})_{\Omega_f} - (\operatorname{div} \mathbf{v}, p_h)_{\Omega_f} = - \sum_{j=1,2} (\mathbf{v} \cdot \mathbf{n}_f, \lambda_{h,j})_{\gamma_j}, & \mathbf{v} \in \mathbf{Z}_{h,f}, \\ & (\operatorname{div} \mathbf{u}_h, r)_{\Omega_i} = (q_i, r)_{\Omega_i}, & r \in N_{h,i}, \quad i = 1, 2, f, \\ & (\mathbf{u}_{h,1} \cdot \mathbf{n}_1 + \mathbf{u}_{h,f} \cdot \mathbf{n}_f, \mu_{h,1})_{\gamma_1} = 0, & \mu_{h,1} \in \Lambda_h, \\ & (\mathbf{u}_{h,2} \cdot \mathbf{n}_2 + \mathbf{u}_{h,f} \cdot \mathbf{n}_f, \mu_{h,2})_{\gamma_2} = 0, & \mu_{h,2} \in \Lambda_h. \end{aligned}$$

5.3. The discrete model problem. Now we write the discretization of the model problem (4.7) using the spaces of approximation defined in the previous section. Let

$$\mathbf{W}_{h,\gamma} \times \Lambda_h \subset H(\operatorname{div}_\tau; \gamma) \times L^2(\gamma)$$

be the usual Raviart–Thomas mixed finite element space of lowest order defined in the $(n - 1)$ -dimensional interface γ . We then define the spaces of approximation of the spaces $\mathbf{W} \times M$ set in section 4.2. Let

$$\mathbf{W}_h = \bigoplus_{i=1,2} \mathbf{Z}_{h,i} \oplus \mathbf{W}_{h,\gamma}, \quad M_h = \bigoplus_{i=1,2} N_{h,i} \oplus \Lambda_h.$$

The discrete mixed model problem then becomes the following (with homogeneous Dirichlet boundary conditions):

$$(5.2) \quad \begin{aligned} & \text{Find } \mathbf{u}_h^m \in \mathbf{W}_h, p_h^m \in M_h && \text{such that} \\ & \alpha_\xi(\mathbf{u}_h^m, \mathbf{v}) - \beta(\mathbf{v}, p_h^m) = 0 && \forall \mathbf{v} \in \mathbf{W}_h, \\ & \beta(\mathbf{u}_h^m, r) = L_q(r) && \forall r \in M_h. \end{aligned}$$

5.4. Link between transmission and model problems. With these spaces and Hypothesis 1, one can simply eliminate two unknowns of the transmission problem: first, the normal component of the Darcy velocity in the fracture can be computed as a function of the Darcy velocities in the neighboring subdomains from the continuity of the fluxes across the interfaces γ_1 and γ_2 . Second, one can eliminate the Lagrange multipliers that enforce the continuity of the pressure on γ_1 and γ_2 . This

is done with the equation expressing Darcy’s law in the fracture written for a test function normal to the fracture. This can be done in two different ways yielding two different parameters, $\xi = 1$ and $\xi = 2/3$; see section 5.5.

After these eliminations we obtain a new system of equations, the model problem (4.7). We illustrate this at an algebraic level in section 5.5.

5.5. The algebraic system. The discretization of the transmission problem in a mixed weak form (5.1) yields the following symmetric system (5.3). In this section, we do not write the right-hand side explicitly, because it is of no interest to our purpose here.

$$(5.3) \quad \begin{bmatrix} A_1 & B_1^\top & 0 & 0 & 0 & 0 & E_1^\top & 0 \\ B_1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & A_2 & B_2^\top & 0 & 0 & 0 & E_2^\top \\ 0 & 0 & B_2 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & A_f & B_f^\top & D_1^\top & D_2^\top \\ 0 & 0 & 0 & 0 & B_f & 0 & 0 & 0 \\ E_1 & 0 & 0 & 0 & D_1 & 0 & 0 & 0 \\ 0 & 0 & E_2 & 0 & D_2 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} U_1 \\ P_1 \\ U_2 \\ P_2 \\ U_f \\ P_f \\ TP_1 \\ TP_2 \end{bmatrix} = \begin{bmatrix} 0 \\ * \\ 0 \\ * \\ 0 \\ * \\ 0 \\ 0 \end{bmatrix}$$

Here, $U_j, j = 1, 2, f$ (and $P_j, j = 1, 2, f$), represent the velocity (respectively, pressure) unknowns in the subdomains $\Omega_j, j = 1, 2, f$. TP_1 and TP_2 are the Lagrange multipliers (trace-of-pressure unknowns) living on the interfaces $\gamma_i, i = 1, 2$. The first pair of equations in (5.3) represents Darcy’s law and the conservation equation in Ω_1 . The matrix E_1^\top ensures the Dirichlet boundary condition on the interface γ_1 . The second pair of equations is the same as the previous pair, but this time in Ω_2 . The third pair of equations is the same in the domain Ω_f , except here there are two matrices D_1^\top and D_2^\top for the source term. So far, all these equations enforce continuity of the pressure across the interfaces γ_1 and γ_2 through the Lagrange multipliers TP_1 and TP_2 . The last two equations, respectively, enforce continuity of the velocities at the interfaces γ_1 and γ_2 .

We decompose the velocities in the fracture U_f into a tangential component U_f^τ and a normal component $U_f^n = [U_{f,1}^n | U_{f,2}^n]^\top$, which is itself split into a part based on the interface γ_1 and the other on γ_2 . (We recall that we have assumed that there is only one strip of cells along the fracture.)

With this notation, the third pair of equations in (5.3) becomes (5.4), where the symmetric matrix A_f is also split into tangential and normal parts,

$$(5.4) \quad \begin{bmatrix} \begin{bmatrix} A_f^\tau & 0 & 0 \\ 0 & A_{f,11}^n & A_{f,12}^n \\ 0 & A_{f,21}^n & A_{f,22}^n \end{bmatrix} & \begin{bmatrix} B_f^{\tau,\top} \\ B_{f,1}^{n,\top} \\ B_{f,2}^{n,\top} \end{bmatrix} & \begin{bmatrix} 0 \\ D_{11}^\top \\ 0 \end{bmatrix} & \begin{bmatrix} 0 \\ 0 \\ D_{22}^\top \end{bmatrix} \\ \begin{bmatrix} B_f^\tau & B_{f,1}^n & B_{f,2}^n \end{bmatrix} & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} U_f^\tau \\ U_{f,1}^n \\ U_{f,2}^n \\ P_f \\ TP_1 \\ TP_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ * \\ 0 \\ 0 \end{bmatrix}.$$

To obtain the discretization of the model problem (4.1) with $\xi = 2/3$, it suffices to eliminate the following unknowns: the normal velocity in the fracture U_n and the two Lagrange multipliers TP_1 and TP_2 .

It is easily seen that D_{11} and D_{22} are square and invertible. In the case of RT_0 spaces, these matrices are actually the identity. So, we first use the last pair of equations in (5.3) to compute $U_{f,1}^{\mathbf{n}}$ and $U_{f,2}^{\mathbf{n}}$ as functions of U_1 and U_2 ,

$$U_{f,i}^{\mathbf{n}} = D_{ii}^{-1} E_i U_i, \quad i = 1, 2.$$

Plugging $U_{f,i}^{\mathbf{n}}$, $i = 1, 2$, into the last equation in (5.4), we get the conservation equation for the model problem,

$$B_f^{\top} U_f^{\top} + \sum_{i=1,2} B_{f,i}^{\mathbf{n}} D_{ii}^{-1} E_i U_i = *.$$

Next, we eliminate TP_i , $i = 1, 2$, from the second and third equations of (5.4) and obtain the following:

$$TP_i = D_{ii}^{-\top} \sum_{j=1,2} A_{f,ij}^{\mathbf{n}} D_{jj}^{-1} E_j U_j + D_{ii}^{-\top} B_{f,i}^{\mathbf{n},\top} P_f, \quad i = 1, 2.$$

We thus obtain the symmetric system (5.5). This system corresponds to the discrete model problem (5.2) when the parameter $\xi = 2/3$,

$$(5.5) \quad \begin{bmatrix} \tilde{A}_1 & B_1^{\top} & \tilde{C}^{\top} & 0 & 0 & \tilde{F}_1^{\top} \\ B_1 & 0 & 0 & 0 & 0 & 0 \\ \tilde{C} & 0 & \tilde{A}_2 & B_2^{\top} & 0 & \tilde{F}_2^{\top} \\ 0 & 0 & B_2 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & A_f^{\top} & B_f^{\top,\top} \\ \tilde{F}_1 & 0 & \tilde{F}_2 & 0 & B_f^{\top} & 0 \end{bmatrix} \begin{bmatrix} U_1 \\ P_1 \\ U_2 \\ P_2 \\ U_f^{\top} \\ P_f \end{bmatrix} = \begin{bmatrix} 0 \\ * \\ 0 \\ * \\ 0 \\ * \end{bmatrix}$$

with

$$\tilde{A}_i = A_i + E_i^{\top} A_{f,ii}^{\mathbf{n}} D_{ii}^{-1} E_i, \quad \tilde{F}_i = B_{f,i}^{\mathbf{n}} D_{ii}^{-1} E_i, \quad i = 1, 2,$$

and

$$\tilde{C} = E_2^{\top} D_{22}^{-\top} A_{f,21}^{\mathbf{n}} D_{11}^{-1} E_1.$$

In this system (5.5), the terms \tilde{A}_i and \tilde{F}_i^{\top} , $i = 1, 2$, ensure a Robin type boundary condition on the interface γ_i , $i = 1, 2$. The unusual coupling term \tilde{C} disappears when using a quadrature rule that kills the extra block-diagonal terms $A_{f,21}^{\mathbf{n}} = A_{f,12}^{\mathbf{n},\top}$ in $A_f^{\mathbf{n}}$. This is what happens when the parameter ξ is equal to 1, which amounts to a finite volume modeling (see [8], for instance).

Conclusion. The two systems (5.5) and (5.3) are equivalent. The system (5.5) represents exactly the discretization of model problem (4.7) when the parameter $\xi = 2/3$ (or $\xi = 1$ with a finite volume discretization).

5.6. Error estimates. We have shown that the two algebraic systems (5.3) and (5.5) are equivalent, under the hypothesis concerning the spaces of approximation and the mesh. Therefore, the error estimates that hold for the transmission problem also hold for the model problem, when the parameter $\xi = 2/3$.

We obtain the error estimate (5.6) below. If \mathcal{T}_h is a regular family of triangulations of Ω respecting Hypothesis (1), there exists a constant C independent of h and d , such

that if the mixed solution (\mathbf{u}, p) of the original problem (2.1) is such that $(\mathbf{u}, p) \in (H^1(\Omega))^n \times H^1(\Omega)$ and $\text{div } \mathbf{u} \in H^1(\Omega)$, and if (\mathbf{u}_h, p_h) in $\mathbf{Z}_h \times N_h$ is the solution to the discrete problem (5.1), we have the standard error estimate

$$(5.6) \quad \|\mathbf{u} - \mathbf{u}_h\|_{\mathcal{H}(\text{div}, \Omega)} + \|p - p_h\|_{L^2(\Omega)} \leq C \max\{h, d\}(|p|_{1, \Omega} + |\mathbf{u}|_{1, \Omega} + |\text{div } \mathbf{u}|_{1, \Omega}).$$

We denote by $(\mathbf{u}_h^m, p_h^m) = ((\mathbf{u}_{h,1}^m, \mathbf{u}_{h,2}^m, \mathbf{u}_{h,f}^m), (p_{h,1}^m, p_{h,2}^m, p_{h,f}^m))$ the solution to the discrete model problem (5.2). The solution (\mathbf{u}_h^m, p_h^m) that lives in $\mathbf{W}_h \times M_h$ is extended to a function $(\tilde{\mathbf{u}}_h^m, \tilde{p}_h^m)$ that lives in $\mathbf{Z}_h \times N_h$. This is simply done in (5.7). We define the constant extension from γ to $\Omega_f : E_f : L^2(\gamma) \rightarrow L^2(\Omega_f)$, $E_f(p) = p \otimes 1_{[-d/2, d/2]}$, where $1_{[-d/2, d/2]}$ is the characteristic function of the segment $[-d/2, d/2]$,

$$(5.7) \quad \begin{aligned} \tilde{\mathbf{u}}_{h,i}^m &= \mathbf{u}_{h,i}^m && \text{in } \Omega_i, \quad i = 1, 2, \\ \tilde{p}_{h,i}^m &= p_{h,i}^m && \text{in } \Omega_i, \quad i = 1, 2, \\ \tilde{\mathbf{u}}_{h,f}^m &= \left([|\mathbf{u}_{h,i}^m \cdot \mathbf{n}_i|_\gamma] \frac{x}{d} + \{\mathbf{u}_{h,i}^m \cdot \mathbf{n}_i|_\gamma\}; \frac{1}{d} E_f \mathbf{u}_{h,f}^m \right) && \text{in } \Omega_f = \left[-\frac{d}{2}, \frac{d}{2} \right] \times \gamma, \\ \tilde{p}_{h,f}^m &= E_f p_{h,f}^m && \text{in } \Omega_f = \left[-\frac{d}{2}, \frac{d}{2} \right] \times \gamma. \end{aligned}$$

In (5.7), the expression $[|\mathbf{u}_{h,i}^m \cdot \mathbf{n}_i|_\gamma]$ (respectively, $\{\mathbf{u}_{h,i}^m \cdot \mathbf{n}_i|_\gamma\}$) represents the jump of the normal velocity (respectively, the mean velocity from Ω_1 to Ω_2) on the interface $\gamma = \partial\Omega_1 \cap \partial\Omega_2$. The extension of the velocity from γ to Ω_f is thus composed of a linear approximation in the normal direction (first component along the Ox axis) and a constant extension of the tangential component. It is not difficult to see that such an extension lives in \mathbf{Z}_h .

Finally, we have seen in section 5.5 that the algebraic solution of the discrete model problem (5.2) and of the original discrete problem (5.1) were the same, in the sense that $(\mathbf{u}_h, p_h) = (\tilde{\mathbf{u}}_h^m, \tilde{p}_h^m)$. So this yields the error estimate (5.8) for the discrete model problem,

$$(5.8) \quad \|\mathbf{u} - \tilde{\mathbf{u}}_h^m\|_{\mathcal{H}(\text{div}, \Omega)} + \|p - \tilde{p}_h^m\|_{L^2(\Omega)} \leq C \max\{h, d\}(|p|_{1, \Omega} + |\mathbf{u}|_{1, \Omega} + |\text{div } \mathbf{u}|_{1, \Omega}).$$

Remark. This error estimate (5.8) has a limitation: in some cases, the solution of a fractured problem has little regularity. In these cases, the constant in the estimate may become very large and delay the convergence. This is probably what happens in section 6.3, where the permeability jumps are large.

Remark. This error estimate (5.8) holds as well when the parameter $\xi = 1$ because one gets the same error estimates from a finite volume discretization.

Remark. In the thin subdomain Ω_f , the cells are in general very long and narrow. This can produce large errors, but in [13] it was pointed out that the mixed finite element method behaves well even when the cells are thus stretched. Hence the estimates (5.6) and therefore (5.8) remain significant despite the thin subdomain Ω_f .

6. Numerical results. Some numerical results are given in this section in order to illustrate the properties of the model presented in this paper. In the first test case (see section 6.1), we show that the model presented in this paper gives good results under the hypotheses that were made to derive the former model (see [2]): velocity jumps across the fracture that can occur when the tangential permeability is large are properly modeled. In the second test case (see section 6.2), one can see that this improved model is able to properly handle a geological barrier (with a small

FIG. 6.1. Left: Dirichlet test case with two permeability tensors in the fracture. Right: Neumann test case. Homogeneous Neumann boundary conditions are depicted with fat lines. The spatial extension of the fracture is depicted with dashed lines.

normal permeability in the fracture). It is shown that this was not possible with the former model. The third test case (see section 6.3) is more difficult: it combines the two previous classes of problems. In the third test case, the fracture has anisotropic permeabilities, thus creating a zone where neither the pressure nor the velocities is continuous across the fracture. These two very stiff test cases show an influence of the parameter ξ , and also show that the model can tackle—when the fracture width is small enough—these types of problems quite reasonably.

The discrete relative L^2 errors are computed in the following way. A direct two-dimensional computation is performed with a mixed hybrid method on a fine mesh \mathcal{T}_η (η being the mesh size, sufficiently small ($\leq 1/200$)). This gives a “reference” pressure P_η^* that we assume to be a “good” approximation to the solution. We present this pressure, for instance, in Figure 6.2, where the grid is considerably coarsened for picture purposes. Note that the grid is locally refined around the fracture. We call P_h^m the solution computed with the model presented in this paper. We use a square mesh with a mesh size h ($> \eta$) in each subdomain, and a one-dimensional mesh in the fracture (with the same mesh size h). We call $\Pi_\eta P_h^m$ its projection onto the fine mesh \mathcal{T}_η . The square of the error is then equal to

$$\|P_h^m - P_\eta^*\|_{L_h^2(\Omega)}^2 = \frac{\sum_{C_\eta \in \mathcal{T}_\eta} (\Pi_\eta P_h^m - P_\eta^*)^2 \text{meas}(C_\eta)}{\sum_{C_\eta \in \mathcal{T}_\eta} (P_\eta^*)^2 \text{meas}(C_\eta)},$$

where \mathcal{T}_η is the fine mesh and $\text{meas}(C_\eta)$ the measure of the cell C_η .

6.1. First test case: Large permeability in the fracture and Dirichlet boundary conditions. The test case is described in Figure 6.1 (left figure). The lengths of the domain along the Ox and Oy axes are, respectively, $L_x = 2, L_y = 1$. The permeability tensor in the fracture depends on a parameter K_f . The permeability in the other subdomains is constant and isotropic: $\mathbf{K} = \mathbf{Id}$, where \mathbf{Id} is the two-dimensional identity matrix. The fracture width is denoted by d . Dirichlet conditions hold on the fracture boundaries. Finally, in this test case, the permeability tensors in the fracture are given by

$$\mathbf{K}_{f1} = \mathbf{K}_{f2} = \begin{bmatrix} K_f & 0 \\ 0 & K_f \end{bmatrix} = K_f \mathbf{Id},$$

where K_f is a parameter greater than 1. This means that the fluid tends to flow rapidly along the fracture.

FIG. 6.2. First test case. Reference pressure (left) and Darcy velocity (right) given by a locally refined mesh computation. $K_f = 100$, $d = 0.01$. (The grid is very coarse for picture purposes.)

FIG. 6.3. First test case. Pressure (left) and Darcy velocity (right) given by the model. $K_f = 100$, $d = 0.01$, $\xi = 2/3$.

One can see a reference computation performed with a locally refined mesh in Figure 6.2. One example of a solution given by the model is shown in Figure 6.3.

Most of the figures plotting the L^2 error that follow can be interpreted in three ways: first, for a constant mesh size h , we can see the dependence of the model when d tends to 0 (“horizontal” curves). Second, for a constant fracture width d (“vertically”), one can see the convergence of the discrete model solution toward the reference solution. Third, one can see the influence of the parameter ξ . The convergence rate was plotted for four values: $\xi = 0.5, 2/3, 1, 10$. In sections 6.1 and 6.2, there is little influence of the parameter ξ .

For instance, in Figure 6.4 (left figure), the L^2 errors are plotted as a function of the fracture width d , with $K_f = 1/d$, for different values of ξ and for different mesh sizes. Here the curves can be interpreted in three ways: first, for a constant h we can hardly see any convergence when d tends to 0. Actually, this is normal as the model depends very little on d , but depends on the product $K_f d$ that is constant in this test case. Second, for a constant d (small enough: $< 1E - 2$), when h is divided by a factor 2, the L^2 error is divided by a constant factor that is close to 2. The discrete model solution converges as $\mathcal{O}(\max\{h, d\})$ toward the reference solution: this confirms the previously stated error estimate. The parameter $\xi \leq 1$ has little influence on the

FIG. 6.4. First test case. Discrete relative L^2 error variation as a function of the fracture width d for different values of ξ . $\xi = 0.51$ in solid line, $\xi = 2/3$ in dashed line, $\xi = 1$ in dotted line, and $\xi = 10$ in dash-dotted line. The five sets of curves show the dependency over the mesh size. From the upper curves to the lower ones: $h = 1/10$, $h = 1/20$, $h = 1/40$, $h = 1/80$, and $h = 1/160$. Left: The fracture permeability varies as $1/d$. The permeability increases as the fracture width decreases: $K_f \times d = 1$. Right: The fracture permeability is constant: $K_f = 100$.

solution given by the model in this case. Still, one should not take ξ greater than 1 as in general it degrades the solution.

The behavior of the solution when the fracture width varies for a fixed fracture permeability is shown in Figure 6.4 (right figure). The L^2 error picture shows again a convergence in $\mathcal{O}(\max\{h, d\})$.

6.2. Second test case: Small permeability in the fracture and Neumann boundary conditions. The test case is described in Figure 6.1 (right figure). The permeability outside the fracture is again equal to the identity: $\mathbf{K} = \mathbf{Id}$. There is a low permeability fracture in the middle of the domain. Homogeneous Neumann conditions are imposed at the upper and lower parts of the fracture. The permeability tensor in the fracture is given by

$$\mathbf{K}_{f1} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \text{ and } \mathbf{K}_{f2} = \begin{bmatrix} K_f & 0 \\ 0 & K_f \end{bmatrix},$$

where K_f is a parameter smaller than 1. Obviously, the fluid tends to avoid the fracture that represents a geological barrier.

As a reference, one can see the result of a computation performed with a mesh that is refined around the fracture in Figure 6.5. One example of a solution given by the model is shown in Figure 6.7. For comparison, a result given by the previous model (with a pressure assumed to be continuous across the fracture (see [2])) is shown in Figure 6.6. The result given by the previous model is not satisfactory.

The behavior of the solution when the fracture width and the permeability vary in the same manner is shown in Figure 6.8 (left figure). There is little dependence of K_f/d (which is constant in the model). The behavior of the solution when the fracture width varies for a fixed fracture permeability is shown in Figure 6.8 (right figure).

FIG. 6.5. *Second test case. Reference pressure (left) and Darcy velocity (right) given by a locally refined mesh computation. $K_f = 2e - 3$, $d = 0.01$.*

FIG. 6.6. *Second test case. Pressure (left) and Darcy velocity (right) given by the OLD model. $K_f = 2e - 3$, $d = 0.01$. This result is obviously not satisfactory.*

FIG. 6.7. *Second test case. Pressure (left) and Darcy velocity (right) given by the model. $K_f = 2e - 3$, $d = 0.01$, $\xi = 2/3$.*

FIG. 6.8. *Second test case. Discrete relative L^2 error variation as a function of the fracture width d for different values of ξ . $\xi = 0.51$ in solid line, $\xi = 2/3$ in dashed line, $\xi = 1$ in dotted line, and $\xi = 10$ in dash-dotted line. The five sets of curves show the dependence on the mesh size. From the upper curves to the lower ones: $h = 1/10$, $h = 1/20$, $h = 1/40$, $h = 1/80$, and $h = 1/160$. Left: The fracture permeability varies as d . The permeability decreases like the fracture width: $K_f/d = 1$. Right: The fracture permeability is constant: $K_f = 0.01$.*

6.3. Third test case: Two anisotropic permeabilities in the fracture and Dirichlet boundary conditions. This is the same test case as in section 6.1 (see Figure 6.1 (left figure)), with a modification in the permeability tensor in the fracture. Dirichlet conditions hold on the fracture boundaries and there are two different anisotropic permeability tensors,

$$\mathbf{K}_{f1} = \begin{bmatrix} 1/K_f & 0 \\ 0 & K_f \end{bmatrix} \text{ and } \mathbf{K}_{f2} = \begin{bmatrix} K_f & 0 \\ 0 & 1/K_f \end{bmatrix},$$

where K_f is a parameter greater than 1. This means that in the middle part of the fracture where the permeability is equal to \mathbf{K}_{f2} , the fluid cannot flow along the fracture but can easily cross it. It is the opposite in the upper and lower parts of the fracture.

Some reference results can be seen in Figure 6.9. Some examples of solutions given by the model for different parameters ξ are shown in Figures 6.10 and 6.11. One can notice that, in this test case, the model does not correctly approach the reference solution everywhere. This is especially true in the regions close to the fracture, where the permeability tensor is \mathbf{K}_{f1} (extremities of the fracture). It might be due to the high singularities at the exits of the fractures. All the results given by the model strongly depend on the parameter ξ , and none of them are completely satisfactory. The lowest errors are generally provided for $\xi = 0.51$, but the model with this parameter does not respect the maximum principle: pressures greater than 1 are computed. And for ξ greater than 1, the L^2 errors are very large. The best compromise seems to be $\xi = 2/3$ in this example: the maximum principle is respected and the error remains reasonable.

The behavior of the solution is shown in Figure 6.12, when d tends to 0 with a constant product $K_f d$. The solution given by the model is almost independent of $K_f d$. In Figure 6.13, the error is plotted as a function of d for two constant values of K_f . In all these curves, one must note that the error is relatively large in comparison to the previous test cases.

FIG. 6.9. Third test case. Reference pressure (left) and Darcy velocity (right) given by a locally refined mesh computation. $K_f = 200$, $d = 0.01$.

FIG. 6.10. Third test case. Pressure (left) and Darcy velocity (right) given by the model. $K_f = 200$, $d = 0.01$, $\xi = 2/3$.

FIG. 6.11. Third test case. Pressure given by the model. Left: $\xi = 0.49$; the parameter ξ is smaller than the stability limit; the model is not stable when $\xi < 1/2$; scales for the pressure are $[-1, 2]$. Right: $\xi = 0.51$; small overshoots and undershoots appear at the boundary of the fracture. $K_f = 200$, $d = 0.01$.

FIG. 6.12. Third test case. Discrete relative L^2 error variation as a function of the fracture width, the fracture permeability parameter varying as $1/d$, for different values of ξ . $\xi = 0.51$ in solid line, $\xi = 2/3$ in dashed line, $\xi = 1$ in dotted line, and $\xi = 10$ in dash-dotted line. The fracture permeability varies as $1/d$; the permeability parameter increases as the fracture width decreases: $K_f \times d = 1$. $n_x = 160$, $h = 6.25E - 3$. Mind the error scales: From 0.1% up to 20%, errors remain at a quite high level.

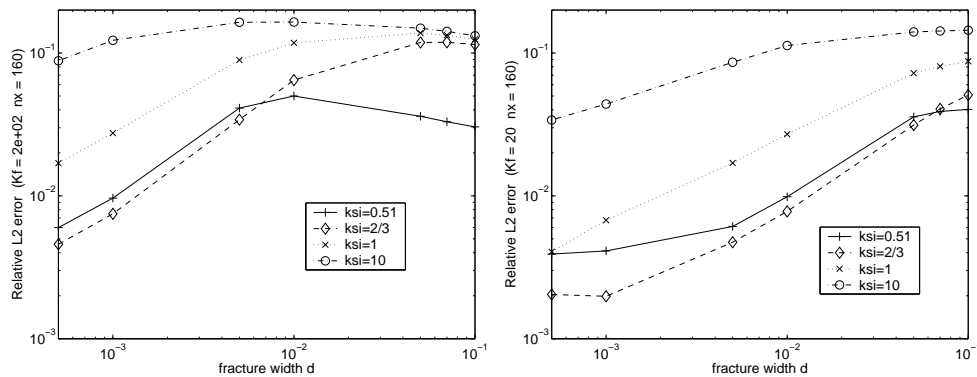

FIG. 6.13. Third test case. Discrete relative L^2 error variation as a function of the fracture width, for different values of ξ . $\xi = 0.51$ in solid line, $\xi = 2/3$ in dashed line, $\xi = 1$ in dotted line, and $\xi = 10$ in dash-dotted line. The fracture permeability parameter is constant. Left: $K_f = 200$. Right: $K_f = 20$. For both figures, $n_x = 160$, $h = 6.25E - 3$. Mind the error scales: From 0.1% up to 20%, errors remain at a quite high level.

7. Domain decomposition. In this section we present a way of efficiently solving the problem arising from the model (4.1).

7.1. Domain decomposition formulation. The direct mixed discretization of problem (4.1) given in (5.2) yields the algebraic system (5.5). As this system (5.5) is not positive definite and is very large, it is expensive to solve. The goal then is to eliminate some of the unknowns to obtain a problem easier to solve.

When the parameter $\xi = 1$, the model problem reduces to the nonlocal nonstandard positive definite interface problem (7.6). For other values of the parameter ξ , it is not yet clear what to do (see (7.3)).

Throughout this section, for simplicity, we will assume that homogeneous Dirichlet boundary conditions are imposed on $\partial\Omega$. We introduce the discrete Dirichlet to Neumann operators S_1 and S_2 in (7.1) for the subdomains Ω_1 and Ω_2 (analogous to

the discrete Steklov–Poincaré operator, except here they include the source term),

$$(7.1) \quad \begin{aligned} S_i &: \Lambda_h \times N_{h,i} \rightarrow \Lambda_h, & i = 1, 2, \\ S_i(\lambda_i, q_i) &= -\mathbf{u}_i \cdot \mathbf{n}_i, \end{aligned}$$

so that

$$(7.2) \quad \begin{aligned} \operatorname{div} \mathbf{u}_i &= q_i && \text{in } \Omega_i, \\ \mathbf{u}_i &= -\mathbf{K}_i \nabla p_i && \text{in } \Omega_i, \\ p_i &= 0 && \text{on } \Gamma_i, \\ p_i &= \lambda_i && \text{on } \gamma. \end{aligned}$$

In terms of these operators, the problem to be solved, (4.1), becomes

$$(7.3) \quad \begin{aligned} S_1(\lambda_1, q_1) + S_2(\lambda_2, q_2) - \operatorname{div}_\tau(\mathbf{K}_{f,\tau} d \nabla_\tau p_f) &= q_f, \\ \xi S_1(\lambda_1, q_1) + \alpha_f \lambda_1 - (1 - \xi) S_2(\lambda_2, q_2) - \alpha_f p_f &= 0, \\ -(1 - \xi) S_1(\lambda_1, q_1) + \xi S_2(\lambda_2, q_2) + \alpha_f \lambda_2 - \alpha_f p_f &= 0, \end{aligned}$$

and it is not obvious how to solve this problem.

If $\xi = 1$, we can express separately λ_1 and λ_2 as functions of p_f . In this case, we replace the Dirichlet to Neumann operators by the discrete Robin to Neumann operators \bar{S}_i defined by (7.4),

$$(7.4) \quad \begin{aligned} \bar{S}_i &: \Lambda_h \times N_{h,i} \rightarrow \Lambda_h, & i = 1, 2, \\ \bar{S}_i(\lambda_i, q_i) &= -\mathbf{u}_i \cdot \mathbf{n}_i, \end{aligned}$$

so that

$$(7.5) \quad \begin{aligned} \operatorname{div} \mathbf{u}_i &= q_i && \text{in } \Omega_i, \\ \mathbf{u}_i &= -\mathbf{K}_i \nabla p_i && \text{in } \Omega_i, \\ p_i &= 0 && \text{on } \Gamma_i, \\ -\mathbf{u}_i \cdot \mathbf{n}_i + \alpha_f p_i &= \alpha_f \lambda_i && \text{on } \gamma. \end{aligned}$$

Then with $\xi = 1$, problem (4.1) becomes the simpler interface problem (7.6) that depends on one scalar unknown, p_f , that lives on the interface:

$$(7.6) \quad \bar{S}_1(p_f, q_1) + \bar{S}_2(p_f, q_2) - \operatorname{div}_\tau(\mathbf{K}_{f,\tau} d \nabla_\tau p_f) = q_f.$$

We recall here that the fracture data are present in two different ways in (7.6). First, the product $\mathbf{K}_{f,\tau} d$ plays the role of a mean permeability for the Darcy law equation along the fracture. Also, the operators \bar{S}_i , $i = 1, 2$, are Robin to Neumann operators with a specific Robin coefficient that depends on the quotient $\mathbf{K}_{f,n}/d$.

7.2. Weak formulation. It is well known that the Dirichlet to Neumann operators $S_i(\cdot, 0)$, $i = 1, 2$, defined in (7.1), are symmetric positive semidefinite (see [9], [5]). We show that this property also holds for the operators defined in (7.4).

LEMMA 7.1. *If the Robin coefficient is positive ($\alpha_f > 0$), the discrete Robin to Neumann operators $\bar{S}_i(\cdot, 0)$ are symmetric positive semidefinite on Λ_h for $i = 1, 2$.*

Proof. Define the bilinear operators

$$(7.7) \quad \begin{aligned} \bar{s}_i &: \Lambda_h \times \Lambda_h \rightarrow \Lambda_h, & i = 1, 2, \\ \bar{s}_i(\lambda, \mu) &= \langle \bar{S}_i(\lambda, 0), \mu \rangle = (\mu, \mathbf{u}_{h,i}(\lambda) \cdot \mathbf{n}_i)_\gamma, & i = 1, 2, \end{aligned}$$

with $\mathbf{u}_{\mathbf{h},i}(\lambda)$ the solution of (7.8) in Ω_i , $i = 1, 2$.

Given λ in Λ_h , seek $\mathbf{u}_{\mathbf{h},i}(\lambda) \in \mathbf{Z}_{\mathbf{h},i}$ and $p_{h,i} \in N_{h,i}$, such that for $\mathbf{v} \in \mathbf{Z}_{\mathbf{h},i}$ and $r \in N_{h,i}$,

$$(7.8) \quad \begin{aligned} (K_i^{-1} \mathbf{u}_{\mathbf{h},i}(\lambda), \mathbf{v})_{\Omega_i} &= (\operatorname{div} \mathbf{v}, p_{h,i})_{\Omega_i} - \left(\mathbf{v} \cdot \mathbf{n}_i, \lambda + \frac{1}{\alpha_f} \mathbf{u}_{\mathbf{h},i}(\lambda) \cdot \mathbf{n}_i \right)_\gamma, \\ (\operatorname{div} \mathbf{u}_{\mathbf{h},i}(\lambda), r)_{\Omega_i} &= 0. \end{aligned}$$

Take $\mathbf{v} = \mathbf{u}_{\mathbf{h},i}(\mu)$ in (7.8) to see that the operators \bar{s}_i can be expressed as

$$(7.9) \quad \bar{s}_i(\lambda, \mu) = (K_i^{-1} \mathbf{u}_{\mathbf{h},i}(\lambda), \mathbf{u}_{\mathbf{h},i}(\mu))_{\Omega_i} + \left(\frac{1}{\alpha_f^{1/2}} \mathbf{u}_{\mathbf{h},i}(\lambda) \cdot \mathbf{n}_i, \frac{1}{\alpha_f^{1/2}} \mathbf{u}_{\mathbf{h},i}(\mu) \cdot \mathbf{n}_i \right)_\gamma.$$

It is now easy to see that the operators \bar{s}_i , $i = 1, 2$, are symmetric and positive semidefinite. \square

7.3. Solving the system efficiently. In the case $\xi = 1$, a good way to solve the model problem (4.1) is to solve iteratively the linear interface equation (7.6). To do so, a good idea would be to take a standard finite volume discretization of the Laplace operator $(-\operatorname{div}_\tau(\mathbf{K}_{f,\tau} d \nabla_\tau \cdot))$ that yields a symmetric positive semidefinite operator. One has to invert the operator $\bar{S}_1(\cdot, 0) + \bar{S}_2(\cdot, 0) - \operatorname{div}_\tau(\mathbf{K}_{f,\tau} d \nabla_\tau \cdot)$, which is symmetric positive semidefinite as a sum of such operators (actually it is positive definite because of the Dirichlet boundary conditions). Thus a simple conjugate gradient method can be applied.

Preliminary numerical results using this iterative method are promising but could probably be improved by an appropriate preconditioner.

8. Conclusion. The models presented in this paper allow the treatment at the same time in the same model of the case in which there is a small permeability in the fracture, involving a pressure discontinuity, and the case in which there is a large permeability in the fracture, involving a velocity discontinuity. In each case, the models agree with the asymptotic analysis given by Hung and Sánchez-Palencia [11] and Sánchez-Palencia [17]. They also make it possible to treat high anisotropies in the fractures (see section 6.3), though the numerical results are not completely satisfactory and further studies would probably be useful to understand clearly where the solution lives (as neither the scalar unknown nor its normal derivative is continuous at the interface).

Some further work is under way to test a more realistic three-dimensional problem involving two or three intersecting fractures. These tests should also involve the transport equations. Also, a preconditioner for the iterative method described in section 7 will be studied and tested.

Acknowledgment. We would like to thank Magne Espedal¹ for useful discussions and remarks.
